

CriCripto — Communication Protocol for Internet 4.0 (IoT & IoE)

Overview

CriCripto proposes a new communication protocol inspired by TCP/IP, designed for Internet 4.0 (IoT and IoE). Its goal is to eliminate traditional TCP/IP bottlenecks in short-lived and wireless communications.

TCP/IP Limitations

Handshakes, acknowledgments, and retransmissions become bottlenecks in modern environments with millions of intermittent devices.

Conceptual Basis

Inspired by UDP, the CriCripto protocol prioritizes speed and simultaneity while adding contextual consensus, temporal synchronization, and economic value layers.

Value-Oriented Communication

Each message carries data, state, and economic intent, enabling autonomous, near-simultaneous negotiation between objects.

Blockchain Integration

The CriCripto blockchain acts as a settlement and audit layer, keeping communication off-chain for speed and scalability.

Conclusion

The CriCripto protocol lays the foundation for a new value-oriented, high-speed internet where things negotiate with each other.
